transfer between the sulfite moiety and the reducible metal than is metal-sulfur bonding. This is probably to be expected in view of the greater electronegativity of the  $O^{2-}$  species as compared to the  $S^{IV}$  species.

## Mechanistic Information from the Micellar Effect on the Base Hydrolysis of ( $\alpha\beta$ S)-(3-Nitrosalicylato)(tetraethylenepentamine)cobalt(III) Ion

Anadi C. Dash\* and Ramesh C. Nayak

Received October 7, 1985

The kinetics of base hydrolysis of the ( $\alpha\beta$ S)-(tetren)(3NO<sub>2</sub>-salicylato)Co(III) ion has been investigated in the presence and absence of cationic (CTAB) and anionic (SDS) surfactants at  $30.0 \pm 0.1$  °C. The phenoxide form of the complex undergoes aquation in the micellar pseudophase of the surfactants much faster than in the aqueous pseudophase, the effect being much more pronounced for SDS. This supports the internal conjugate base mechanism, the reactive amine conjugate base being generated by the intramolecular proton-transfer equilibrium [(tetren)CoO<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(3NO<sub>2</sub>)O]<sup>+</sup>  $\rightleftharpoons$  [(tetrenN-H)CoO<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(3NO<sub>2</sub>)OH]<sup>+</sup>. The CTAB micelle, however, retards the second-order base hydrolysis of the micelle-bound phenoxide species. The dipositive phenol form of the complex binds strongly to the anionic micelle of SDS, but this does not lead to detectable enhancement of its rate of aquation.

### Introduction

A recent study by A.C.D.<sup>1</sup> elucidated that the base hydrolysis of the phenoxide species of ( $\alpha\beta$ S)-(salicylato)(tetren)Co(III) involved two pathways, namely, the pseudo-first-order OH<sup>-</sup>-independent aquation and the second-order OH<sup>-</sup>-catalyzed base hydrolysis. The rate and activation parameters for the OH<sup>-</sup>-independent path, in comparison to the relevant data for the corresponding species of *cis*-(salicylato)(NH<sub>3</sub>)(en)<sub>2</sub>Co(III) and  $\alpha$ -*cis*-(NH<sub>3</sub>)(salicylato)(trien)Co(III) and related systems (see Table II of ref 1), provided evidence in favor of the internal conjugate base mechanism (ICB) involving the intramolecular phenoxide-assisted generation of the reactive amine conjugate base.<sup>2</sup> A detailed understanding of the ICB mechanism in cobalt(III) and other related systems is at present a rather difficult task due to the lack of data on sufficient number of representative systems.

This paper presents a study of the base hydrolysis of ( $\alpha\beta$ S)-(3NO<sub>2</sub>-salicylato)(tetren)Co(III) in buffered aqueous media in the presence and absence of cationic and anionic surfactants. The purpose was to generate the phenoxide species of the substrate in an aqueous medium and then partition it to the micellar pseudophase of the surfactants so that its reactivity in this phase can be assessed to support the ICB mechanism cited above. A preliminary report on the effect of CTAB on the base hydrolysis of *cis*-(5-nitrosalicylato)(amine)bis(ethylenediamine)cobalt(III)<sup>3</sup> indicated that this dipolar substrate (phenoxide form) exchanged into the micellar pseudophase of CTAB in which it underwent base hydrolysis at a rate slightly faster than in the aqueous phase. However, the binding of this substrate with the CTAB micelle was observed to be weak, and the corresponding rate effect was also small. We chose the (3NO<sub>2</sub>-salicylato)(tetren)Co(III) complex in the present work with the hope of observing enhanced micellar binding of this substrate and hence higher rate effects of the micelles.

### Experimental Section

Tetraethylenepentamine was used as obtained from BDH. The bromide analysis of CTAB indicated that the sample has a purity of

99.8%. Sodium dodecyl sulfate (SDS) (Fluka, AG) was purified by repeated crystallization from ethanol and checked for purity by cmc determination (cmc = 0.008 M).<sup>4</sup> All other chemicals were of AR grade. Sodium perchlorate used for ionic strength adjustment was prepared by neutralizing HClO<sub>4</sub> with NaOH solution.

( $\alpha\beta$ S)-(3-Nitrosalicylato)(tetraethylenepentamine)cobalt(III) perchlorate was prepared from ( $\alpha\beta$ )-chloro(tetraethylenepentamine)cobalt(III) perchlorate as described earlier for the preparation of the corresponding salicylato complex.<sup>1</sup> Anal. Calcd for [Co(C<sub>8</sub>N<sub>5</sub>H<sub>23</sub>)(CO<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)(NO<sub>2</sub>OH)(ClO<sub>4</sub>)<sub>2</sub>]: Co, 9.36; N, 13.35. Found: Co, 9.3; N, 13.2. The spectral parameters of the complex measured by a Varian-Cary UV-visible recording spectrophotometer, Model 634S, are as follows [ $\lambda_{\max}$ , nm ( $\epsilon$ , M<sup>-1</sup> cm<sup>-1</sup>): 492 (181), 310 (9512), and 228 (29368) in 0.01 M HClO<sub>4</sub> medium. These may be compared with corresponding data for the ( $\alpha\beta$ S)-(salicylato)(tetren)Co(III) ion [ $\lambda_{\max}$ , nm ( $\epsilon$ , M<sup>-1</sup> cm<sup>-1</sup>): 491 (170) and 298 (4318)]<sup>1</sup> and for *cis*-(amine)(3-nitrosalicylato)bis(ethylenediamine)cobalt(III) ion [ $\lambda_{\max}$ , nm ( $\epsilon$ , M<sup>-1</sup> cm<sup>-1</sup>): 500 (109) and 312 (6689)].<sup>5</sup>

The pH measurements were made with an Elico digital pH meter, Model LI 120; the reference electrode was filled with saturated NaCl instead of KCl in order to avoid precipitation of KClO<sub>4</sub> and KDS during pH measurements.

The kinetics of hydrolysis of the cobalt(III) substrate was investigated at  $30.0 \pm 0.1$  °C in the pH range  $7.32 \leq \text{pH} \leq 10.1$ . The reaction was initiated by injecting 0.15 mL of stock solution of the complex into the preequilibrated reaction mixture (3 mL) taken in a 10-mm quartz cell placed in the thermostated cell compartment of the spectrophotometer. The mixing time was <15 s. The rate of decrease of absorbance (measured against solvent blank) at 400 or 450 nm was monitored manually or by a Varian 9176 strip chart recorder. Runs were made under pseudo-first-order conditions with  $[\text{complex}]_T = (0.29-3.20) \times 10^{-4}$  M.

### Results and Discussion

The complex ion is remarkably stable to aquation but it undergoes base hydrolysis quite rapidly. In mild alkaline medium, it dissociates to the highly absorbing phenoxide species, [Co(tetren)(O<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(3NO<sub>2</sub>)O)]<sup>+</sup>, which exhibits  $\lambda_{\max}$  at 400 nm with  $\epsilon = 8054$  M<sup>-1</sup> cm<sup>-1</sup> (see Figure 1).

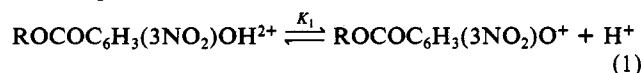

**Figure 1.** Spectral changes during the base hydrolysis of [(tetren)-CoO<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(3NO<sub>2</sub>)OH]<sup>2+</sup> ([complex]<sub>T</sub> = 1.022 × 10<sup>-4</sup> M, 28 °C: (1) 0–140 s, (2) 340–465 s, (3) 900–1050 s, (4) 1845–1977 s, (5) 2460–2590 s, (6) 24 h (pH 8.39 for curves 1–6). (a) Spectrum for hydrolysis in 0.006 M HClO<sub>4</sub>.

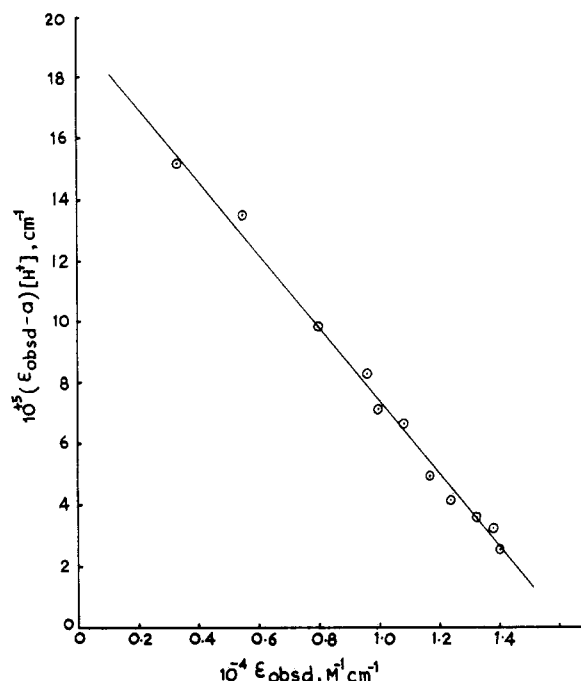

**Figure 2.** Typical  $\ln(A_t - A_\infty)$  vs.  $10^{-2}t$  (s) plot showing the biphasic nature of base hydrolysis (pH 7.6, 30 °C,  $\lambda = 400$  nm).

The pseudo-first-order kinetic plots exhibit an initial curvature (Figure 2) that is attributed to the presence of a more reactive isomer, presumably the ( $\alpha\beta R$ ) isomer in the sample. Resolution of the kinetic plots could be achieved in the pH range  $7.32 \leq \text{pH} \leq 8.70$ . At pH > 8.7, the fast-reacting isomer decays too fast and the initial curvature of the rate plots virtually disappears.  $k_{\text{obsd}}$  for the slow second phase of the reaction could be obtained from the gradients of the plots of  $\ln(A_t - A_\infty)$  against  $t$  (s).  $k_{\text{obsd}}$  values for the fast initial phase of the reaction were obtained by the method of Brown and Fletcher.<sup>7</sup>

**Acid Dissociation Constant ( $K_1$ ) of the Unbound Phenol Group.** The extrapolated zero-time absorbance data ( $\epsilon_{\text{obsd}}$ , M<sup>-1</sup> cm<sup>-1</sup>) for the complex at 400 nm obtained from the fast phase of the reaction at  $7.32 < \text{pH} < 8.7$  were interpreted in terms of the acid dissociation equilibrium

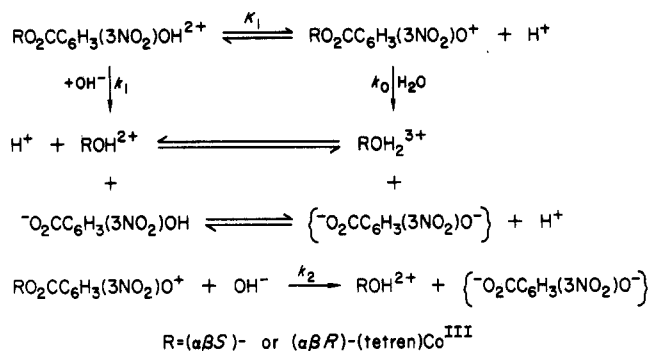

where R denotes (tetren)Co<sup>3+</sup>. The phenoxide species was observed to be due to a relatively stronger absorbing species at the wavelength of measurement. Assuming that the value of  $K_1$  is

**Figure 3.** Determination of dissociation constant of the unbound phenol group:  $10^5(\epsilon_{\text{obsd}} - a)[\text{H}^+]$  (cm<sup>-1</sup>) vs.  $10^{-4}\epsilon_{\text{obsd}}$  (M<sup>-1</sup> cm<sup>-1</sup>) plot.

#### Scheme I

not influenced by the isomer distribution,  $\epsilon_{\text{obsd}}$  can be easily represented as

$$\epsilon_{\text{obsd}} = \{(\epsilon_s A + \epsilon_r)/(1 + A) + [(\epsilon'_s A + \epsilon'_r)/(1 + A)]K_1/[\text{H}^+]\}/(1 + K_1/[\text{H}^+]) \quad (2)$$

where  $A$  = ratio of the concentration of the two isomers in the sample =  $[\alpha\beta S]_T/[\alpha\beta R]_T$ ,  $\epsilon_s$  and  $\epsilon_r$  ( $\epsilon'_s$  and  $\epsilon'_r$ ) denote the molar extinction coefficients of the phenol form (phenoxide form) of the ( $\alpha\beta S$ ) and ( $\alpha\beta R$ ) isomers, respectively. Equation 2 on linearization yields eq 3, where  $a = (\epsilon_s A + \epsilon_r)/(1 + A) = \epsilon_{\text{obsd}}$  in the

$$(\epsilon_{\text{obsd}} - a)[\text{H}^+] = b - K_1 \epsilon_{\text{obsd}} \quad (3)$$

acidic medium and  $b = K_1(\epsilon'_s A + \epsilon'_r)/(1 + A)$ . With  $a = 132 \pm 2$  M<sup>-1</sup> cm<sup>-1</sup> (pH 3)  $\epsilon_{\text{obsd}}$  data were fitted to eq 3 by a least-squares program adopted to an IBM 1130 computer (see Figure 3), and we obtained  $b = (19.7 \pm 0.3) \times 10^{-5}$  cm<sup>-1</sup> and  $K_1 = (1.2 \pm 0.3) \times 10^{-8}$  M (30 °C,  $I = 0.3$  M). The value of  $K_1$  agrees well with that of *cis*-(ammine)(3-nitrosalicylato)bis(ethylenediamine)cobalt(III) ( $\text{p}K_1 = 7.9$ , 28 °C,  $I = 1.0$  M).<sup>5</sup>

**Rate Data in the Absence of Surfactants.**  $k_{\text{obsd}}$  data for both slow ( $\alpha\beta S$ ) and fast ( $\alpha\beta R$ ) reacting isomers are strongly sensitive to pH (see Table I). Scheme I presents the possible reaction pathways for which  $k_{\text{obsd}}$  is given by eq 4, where  $K_w$  denotes the

$$k_{\text{obsd}} = \frac{(k_0 K_1 + k_1 K_w) + k_2 K_1 K_w/[\text{H}^+]}{[\text{H}^+] + K_1} \quad (4)$$

ionic product of water,  $k_i$ 's are the rate constants (see Scheme

<sup>a</sup> 2-Methylimidazole-HClO<sub>4</sub> buffer for pH 8.4–9.1, Tris base-HClO<sub>4</sub> buffer for pH 7.32–8.73; borate buffer for pH 7.86–9.59, and 2-aminoethanol-HClO<sub>4</sub> buffer for pH 9.77–10.12. <sup>b</sup> See eq 3. <sup>c</sup>  $K_1$  was held fixed at this value to calculate errors of other parameters. <sup>d</sup>  $k_1$  path is assumed to be nonexistent. <sup>e</sup>  $k_0$  path is assumed to be nonexistent and  $K_w = 2.58 \times 10^{-14} \text{ M}^2$ ; Harned, H. S.; Owen, B. B. *The Physical Chemistry of Electrolytic Solutions*, 3rd ed., Reinhold: New York, 1958; p 485.

I), and  $K_1$  is as defined earlier (eq 1). The rate data were fitted to eq 4 by a computer program that varied the parameters ( $k_0 K_1 + k_1 K_w$ ),  $k_2 K_1 K_M$ , and  $K_1$  and minimized the sum of the weighted residuals  $\sum [(k_{\text{calcd}} - k_{\text{obsd}})/\sigma(k_{\text{obsd}})]^2$ .  $K_1$  being known, the approximate values of other parameters were judged from the  $k_{\text{obsd}}/([H^+] + K_1)$  against  $[H^+]^{-1}$  plots. The calculated values of the parameters of eq 4 and the optimized values of  $k_0$  and  $k_1$  are given in Table I. It is of interest to note that the fast reacting isomer is  $\approx 30$  times more reactive than the slow reacting isomer ( $k_{\text{fast}}/k_{\text{slow}} = 32.5, 32.8$ , and 25 for  $k_0, k_1$ , and  $k_2$  paths, respectively). A similar reactivity difference is exhibited by ( $\alpha\beta R$ ) and ( $\alpha\beta S$ ) isomers of [(tetren)CoCl]<sup>2+</sup> ( $\alpha\beta R$ ) > ( $\alpha\beta S$ ) in the base hydrolysis path (see Table II of ref 1). The observed trend in the reactivity of the isomers is presumably associated with their strain energies.<sup>8</sup> A comparison of the values of  $k_0$  and  $k_2$  for the slow-reacting isomer with the corresponding data for ( $\alpha\beta S$ )-(salicylato)(tetren)Co(III) ( $k_0 = 0.3 \text{ s}^{-1}$ ,  $k_2 = 5.5 \text{ s}^{-1} \text{ M}^{-1}$  at  $30.1$  °C,  $I = 1.0 \text{ M}$ )<sup>1</sup> reveals a 30 times rate enhancement in the  $k_0$  path with a comparable rate in the  $k_2$  path when 3-nitrosalicylate is replaced by salicylate. The reactivity trend in the  $k_0$  path parallels the basicity of the unbound phenoxide group;  $K_1 = 16.9 \times 10^{-9} \text{ M}$  ( $I = 0.3 \text{ M}$ ,  $30$  °C) and  $13 \times 10^{-12} \text{ M}$  ( $I = 1.0 \text{ M}$ ,  $30$  °C)<sup>9</sup> for 3-nitrosalicylato and salicylato complexes, respectively, in agreement with the operation of an internal conjugate base mechanism, the reactive amine conjugate base being generated by the pendant phenoxide group:

**Effect of CTAB on the Rate of Base Hydrolysis.** Rate data in Table II (Figure 4) demonstrate the rate accelerating effect of [CTAB] in contrast with retardation by [KBr]. The biphasic nature of the kinetic plots virtually disappeared at all concentrations of CTAB used at pH 9. At pH 8, however, such plots did exhibit initial curvature; but sufficient data points were not available for the initial fast phase of the reaction to resolve the

(9) Calculated from the relationship<sup>1</sup>  $K_1 = Q_1 K_w$  for  $K_w = 2.5 \times 10^{-14} \text{ M}^2$  and  $Q_1 = 523 \text{ M}^{-1}$  at  $I = 1.0 \text{ M}$ ,  $30$  °C, where  $Q_1$  is the forward equilibrium constant of the reaction

kinetics with good precision. A qualitative estimate of the effect of [CTAB] on the  $k_{\text{obsd}}(\text{fast})$  value at  $\text{pH } 8.03 \pm 0.01$  is, however, as follows:  $10^2 k_{\text{obsd}}(\text{fast}) = 0.021, 0.03, 0.038, \text{ and } 0.042 \text{ s}^{-1}$  at [CTAB]<sub>T</sub> = 0, 0.01, 0.02, and 0.05 M, respectively. Nevertheless, these data do indicate the rate-accelerating effect of CTAB for the fast-reacting isomer also. Reasonable assumptions to interpret the rate data are as follows: (i) the phenoxide species being dipolar in nature ( $\text{R}^{2+}\text{XO}^-$ ) can be reversibly bound to the cationic micellar pseudophase of the surfactant; (ii) the dipositive phenol form ( $\text{RXOH}^{2+}$ ) exists exclusively in the aqueous pseudophase in equilibrium with its phenoxide form; (iii) the micellar binding equilibrium for the phenoxide species is established rapidly;<sup>10</sup> (iv) the phenoxide species hydrolyzes in the micellar pseudophase much faster than in the aqueous pseudophase. Another very important and useful assumption is that the buffer equilibria in aqueous phase is not appreciably perturbed by the surfactant. This is supported by the constancy of the intermicellar pH of Tris (pH 8) and borate buffers (pH 9).<sup>11,12</sup> A reasonable reaction scheme, therefore, will involve micelle-mediated paths 6 and 7 in addition to those presented in Scheme I.

In reactions 6 and 7, the subscripts W and M stand for the aqueous and micellar pseudophases, respectively, and Dn denotes the micellized surfactant. The spectral measurement indicated that one of the products is 3-nitrosalicylate ion reversibly bound to the micellar pseudophase. The other product was assumed to be  $(\alpha\beta\text{S})\text{--}[(\text{tetren})\text{CoOH}]^{2+}$  since no other cobalt(III) product was obtained in the base hydrolysis reaction in the presence of KBr. At constant pH and under pseudo-first-order conditions of [CTAB]<sub>T</sub>,  $k_{\text{obsd}}$  takes the form

$$k_{\text{obsd}} = \frac{k_{\text{obsd}}^W([\text{H}^+]_W + K_1) + k^M K_1 K_M [\text{Dn}]}{[\text{H}^+]_W + K_1 + K_1 K_M [\text{Dn}]} \quad (8)$$

where  $k_{\text{obsd}} = k_{\text{obsd}}^W$  at [CTAB]<sub>T</sub> = 0, [Dn] = [CTAB]<sub>T</sub> - cmc, and  $k^M$  denotes the pseudo-first-order hydrolysis rate constant for the micellar-bound phenoxide species. The ionic strength of the aqueous pseudophase for both borate and Tris buffer media based on  $\alpha$  (the degree of ionization of the micelle)<sup>12</sup> = 0.2 varies to a small extent ( $I = 0.03 \pm 0.01 \text{ M}$ ) in the range of [CTAB]<sub>T</sub> used. But the rate data under varying [KBr] indicate that the effect of ionic strength on  $k_{\text{obsd}}$  is negligible at  $I < 0.04 \text{ M}$  once pH is held constant. The effect of ionic strength variation was neglected, and the rate data in the presence of CTAB were fitted to eq 9 obtained from eq 8. Cmc was taken to be  $5.0 \times 10^{-4} \text{ M}$

$$(k_{\text{obsd}} - k_{\text{obsd}}^W)^{-1} = (k^M - k_{\text{obsd}}^W)^{-1} + [(k^M - k_{\text{obsd}}^W)K_1 K_M]^{-1}([\text{H}^+]_W + K_1)[\text{Dn}]^{-1} \quad (9)$$

for both buffer systems.<sup>13</sup> The least-squares gradients and intercepts of the double reciprocal plots of  $(k_{\text{obsd}} - k_{\text{obsd}}^W)^{-1}$  against  $[\text{Dn}]^{-1}$  yielded  $k_M = (2.3 \pm 0.2) \times 10^{-3} \text{ s}^{-1}$  and  $K_M = 17.4 \pm 1.9 \text{ M}^{-1}$  at pH 8.03 and  $k_M = (4.0 \pm 0.4) \times 10^{-3} \text{ s}^{-1}$  and  $K_M = 26.6 \pm 1.9 \text{ M}^{-1}$  at pH 9.10  $\pm 0.02$ , using an ionic strength corrected value of  $K_1 = 2.9 \times 10^{-8} \text{ M}$  ( $I = 0.03 \text{ M}$ ).<sup>14</sup> Relatively weaker micellar binding in tris buffer system (pH 8.03) might result from

efficient competition of  $\text{Cl}^-$  (see footnote a in Table II) with the dipolar complex ion for micellar binding. Values of  $K_M$  for binding of substituted phenoxide ions with the CTAB micelle are  $>10^3 \text{ M}^{-1}$ .<sup>15</sup> In the present case the low value of  $K_M$  is due to electrostatic repulsion between the bipositive charge center of the substrate and the cationic micelle, which does not allow the hydrophobic part of the tetren complex (unlike that of the substituted phenoxide ions) to penetrate into the interior of the micelle.

It is, however, worth noting that  $k_M$  is slightly sensitive to pH, indicating thereby that the  $\text{OH}^-$ -catalyzed path is also available to the dipolar complex ion in the micellar pseudophase. The validity of eq 9 also suggests that intramicellar  $[\text{OH}^-]$  ( $[\text{OH}^-]_M$ ) is not appreciably altered in the range of [CTAB]<sub>T</sub> used for both buffer systems and pH conditions. Assuming  $[\text{OH}^-]_M \propto [\text{OH}^-]_W$  an empirical correction is applied as is shown in eq 10, which yields

$$k_M = (k_0)_M + (k_2)_M [\text{OH}^-]_M = (k_0)_M + C(k_2)_M K_W / [\text{H}^+]_W \quad (10)$$

$(k_0)_M = (2.2 \pm 0.2) \times 10^{-3} \text{ s}^{-1}$  and  $C(k_2)_M K_W = 1.44 \times 10^{-12} \text{ s}^{-1} \text{ M}$ , where  $K_W$  is the ionic product of water in the aqueous pseudophase and the constant  $C^{16}$  may be given by

$$C = (1/\bar{V})K_M K_{\text{OH/Br}} [\text{Br}^-]_M / [\text{Br}^-]_W$$

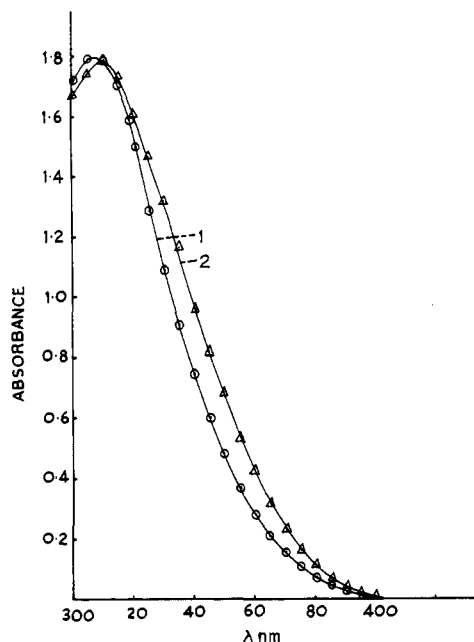

It is to be noted that  $(k_0)_M = k_M$  at pH 8.03;  $(k_2)_M$  turns out to be  $3.5 \text{ M}^{-1} \text{ s}^{-1}$ , taking the selectivity parameter  $K_{\text{OH/Br}} = 0.08$ ,  $K_M = 26.6 \text{ M}^{-1}$ ,  $K_W = 2 \times 10^{-14} \text{ M}^2$  ( $I = 0.03 \text{ M}$ ),  $\bar{V}$  (=partial molar volume of the micellized surfactant) =  $0.37 \text{ L mol}^{-1}$  (calculated),<sup>16</sup> and the mean value of  $[\text{Br}^-]_M / [\text{Br}^-]_W = 3.6$  in borate buffer system. Bunton and co-workers,<sup>18</sup> however, estimated the molar volume of the Stern layer of the micelle of CTAB, in which the exchangeable ions are likely to be present, as  $0.14 \text{ L}$ . Using this value of  $\bar{V}$ , we obtain  $(k_2)_M = 1.3 \text{ M}^{-1} \text{ s}^{-1}$ . The calculated value of  $(k_2)_M / (k_2)_W$  ( $=0.19$  or  $0.07$  for  $\bar{V} = 0.37$  or  $0.14 \text{ L mol}^{-1}$ , respectively) reflects the rate-decelerating effect of the cationic micelle of CTAB on the second-order base hydrolysis path. However, a comparison of the values of  $(k_2)_M$  for the tetren-3NO<sub>2</sub>-salicylate complex with that of *cis*-(NH<sub>3</sub>)-(5NO<sub>2</sub>-salicylate)(en)<sub>2</sub>Co(III) ( $(k_2)_M = 3.1 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1}$  at  $35^\circ \text{C}$ )<sup>20</sup> presumably indicates a relatively stronger micellar effect for the former.

The spontaneous aquation rate constant of  $(\alpha\beta\text{S})[(\text{tetren})\text{CoO}_2\text{C}_6\text{H}_3(3\text{NO}_2)\text{OH}]^{2+}$  is expected to be comparable to that of the corresponding salicylate complex, which is  $(2.0 \pm 0.4) \times 10^{-6} \text{ s}^{-1}$  at  $75^\circ \text{C}$  ( $I = 1.0 \text{ M}$ ).<sup>6</sup> In the absence of the ICB mechanism the aquation rate constant of the tetren-phenoxide species is also expected to be less than that of its phenol form since the former will involve displacement of 3-nitrosalicylate dianion and the latter the corresponding univalent anion from the same cobalt(III) center.<sup>19</sup>

The phenoxide species aquates in the micellar pseudophase of CTAB twice as fast as in the aqueous phase ( $(k_0)_M / (k_0)_W = 2$ , taking the optimized value of  $(k_0)_W = 8.6 \times 10^{-4} \text{ s}^{-1}$ ). The

 (19) Unlike the tetren complex, the  $k_0$  path for *cis*-(NH<sub>3</sub>)-(en)<sub>2</sub>CoO<sub>2</sub>C<sub>6</sub>H<sub>3</sub>(5NO<sub>2</sub>)O<sup>+</sup> in the micellar pseudophase of CTAB was too slow to be detected at comparable temperature.<sup>3</sup> This argues against the pendant phenoxide group assisted hydration of the ester carbonyl followed by the acyl cleavage mechanism usually applicable to organic esters since for both systems comparable rates are expected in the micellar phase. Earlier, we also discounted such a possibility from consideration of the activation parameters.<sup>1</sup>  
 (20) Note that the rate constant in CTAB micelle for the bis(ethylenediamine) complex was reduced to the second-order form<sup>18</sup> ( $(k_2)_M = k_M \times 0.14 \text{ M}^{-1} \text{ s}^{-1}$ ).

**Figure 5.** Effect of SDS on the absorption spectrum of [(tetren)-CoO<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(3NO<sub>2</sub>)OH]<sup>2+</sup> at 30 °C; (1) [SDS] = 0.1, [HClO<sub>4</sub>] = 0.01 M; (2) [SDS] = 0, [HClO<sub>4</sub>] = 0.01 M; [complex]<sub>T</sub> = 2 × 10<sup>-4</sup> M.

rate-accelerating effect may be ascribed to (i) a favorable internal conjugate base equilibrium and (ii) easy expulsion of the positively charged cobalt(III) moiety from the dissociative transition state of the internal conjugate base in the cationic micellar pseudophase of CTAB. In both these processes it is likely that polarity of the microenvironment at the binding site of the micelle plays an important role.

**Binding of [(tetren)CoO<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(3NO<sub>2</sub>)OH]<sup>2+</sup> with the Anionic Micelle of SDS and Its Effect on the Hydrolysis Rate.** Micellar binding of the dipositive complex ion is indicated by the observed spectral changes (see Figure 5). No significant enhancement of the rate of aquation of the phenol species by SDS is indicated. For the micellar binding equilibrium (11),  $\epsilon_{\text{obsd}}$  for the complex is given by eq 12, where  $\epsilon_w$  and  $\epsilon_M$  denote the molar extinction

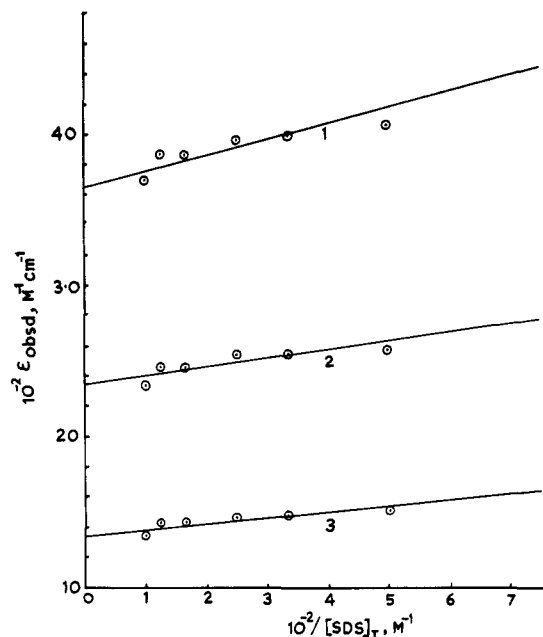

$$\epsilon_{\text{obsd}} = \frac{\epsilon_w + \epsilon_M K_M [\text{Dn}]}{1 + K_M [\text{Dn}]} \quad (12)$$

coefficients of the phenol species in the aqueous and micellar pseudophases, respectively. Equation 12 can be transformed to eq 13 if  $K_M [\text{Dn}] \gg 1$  is satisfied.  $\epsilon_{\text{obsd}}$  data at 340, 350, and 360

$$\epsilon_{\text{obsd}} = \epsilon_w / K_M [\text{Dn}]^{-1} + \epsilon_M \quad (13)$$

nm fit eq 13 satisfactorily (Figure 6) in the range [SDS]<sub>T</sub> = 0.002–0.01 M, taking [Dn] = [SDS]<sub>T</sub>.<sup>21</sup>  $\epsilon_{\text{obsd}}$  leveled off to a constant value at each of these wavelengths in the range 0.015 < [SDS]<sub>T</sub> < 0.1 M. An average value of  $K_M = (5.2 \pm 0.5) \times 10^3 \text{ M}^{-1}$  was obtained from the slopes of the plots of  $\epsilon_{\text{obsd}}$  against [SDS]<sub>T</sub><sup>-1</sup> at 340, 350, and 360 nm. The value of ( $\epsilon_w/\epsilon_M$ ) was found to be 1.36, 1.45, and 1.56 at 340, 350, and 360 nm, respectively. The value of the binding constant, which is significantly higher than the same for substituted phenols,<sup>22</sup> depicts a strong Coulombic interaction between the anionic micelle and the dipositive complex ion.

The effect of SDS on the rate of base hydrolysis of the complex was examined at 30 °C at constant [OH<sup>-</sup>]<sub>T</sub> = 0.0182 and varying

**Figure 6.** 10<sup>2</sup>  $\epsilon_{\text{obsd}}$  (M<sup>-1</sup> cm<sup>-1</sup>) vs. 10<sup>2</sup>/[SDS]<sub>T</sub> (M<sup>-1</sup>) plots. [HClO<sub>4</sub>]<sub>T</sub> = 0.005 M;  $\lambda_{\text{nm}}$  = 340 (1), 350 (2), and 360 (3).

[SDS]<sub>T</sub> = 0.0112, 0.04, 0.06, and 0.12 M ([complex]<sub>T</sub> = 3.8 × 10<sup>-5</sup> M). The rate of formation of the highly absorbing 3-nitrosalicylate dianion was followed at 420 nm. At [SDS]<sub>T</sub> = 0.0112 M, the rate was immeasurably fast. Absorbance–time data at [SDS]<sub>T</sub> = 0.04, 0.06, and 0.12 M yielded good pseudo-first-order kinetic plots from which we obtained SDS-independent  $k_{\text{obsd}} = (4.2 \pm 0.1) \times 10^{-2} \text{ s}^{-1}$ . Hence complete micellar binding is indicated under this condition. For the slow-reacting isomer  $k_{\text{obsd}}$  at [OH<sup>-</sup>]<sub>T</sub> = 0.0182 M and [SDS]<sub>T</sub> = 0 is calculated to be 0.24 s<sup>-1</sup> (calculated  $k_{\text{obsd}} = k_0 + k_2 [\text{OH}^-]_T$ ).<sup>23</sup> Thus unlike CTAB, the anionic surfactant retards the base hydrolysis rate of the complex. This is attributed to the nonavailability of the OH<sup>-</sup>-catalyzed path for the phenoxide species in the anionic micellar pseudophase of SDS. The spontaneous aquation of the phenoxide species in the anionic micellar pseudophase is 20 times faster than in the cationic micelle of CTAB. This is in complete agreement with the ICB mechanism since the unbound phenoxide ion is expected to be a stronger base in the anionic micelle than in the cationic one. The electrostatic effect of the anionic micelle will also favor separation of the anionic species, <sup>-</sup>O<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(3NO<sub>2</sub>)OH, from the cobalt(III) center in the dissociative transition state of the ICB mechanism to cause rate enhancement.

It is, however, of interest to note that the acid dissociation equilibrium of the complex (eq 1) is strongly favored in the direction of the phenol species in the presence of SDS. This is indicated by the disappearance of the absorption maximum of the phenoxide species at 400 nm and appearance of the absorption maximum of the phenol species at 310 nm in the presence of SDS (0.0112–0.12 M) at pH 9.1. The rate constants ( $k_{\text{obsd}}$ ) for the slow phase of the reaction measured by following the rate of decrease of absorbance at 310 nm averaged to  $(1.0 \pm 0.1) \times 10^{-3} \text{ s}^{-1}$  at 0.0112 ≤ [SDS]<sub>T</sub> ≤ 0.12 M, (pH 9.10 ± 0.01, 30 °C).  $k_{\text{obsd}}$  may be taken to be the rate constant in the micellar pseudophase. The apparent retardation of base hydrolysis rate by SDS under mildly alkaline pH conditions ( $k_{\text{obsd}} = (1.76 \pm 0.02) \times 10^{-3} \text{ s}^{-1}$  at [SDS]<sub>T</sub> = 0, pH 9.11 ± 0.01, 30 °C) indicates that a significant proportion of the complex exists in the micellar pseudophase as the unreactive phenol species in equilibrium with its more reactive phenoxide analogue.

**Registry No.** ( $\alpha\beta S$ )-[(tetren)CoO<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(3-NO<sub>2</sub>)OH](ClO<sub>4</sub>)<sub>2</sub>, 101953-43-9; ( $\alpha\beta R$ )-[(tetren)CoO<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(3-NO<sub>2</sub>)OH](ClO<sub>4</sub>)<sub>2</sub>, 101953-45-1; CTAB, 57-09-0; SDS, 151-21-3; KBr, 7758-02-3.

(21) This assumption becomes valid if  $\text{cmc} \ll 0.002 \text{ M}$ . Added salts have been reported to diminish the cmc value of SDS significantly: Cordes, E. H.; Gitter, C. *Prog. Bioorg. Chem.* 1973, 2, 1.

(22) For SDS micelle, the binding constants of a series of para-substituted phenols are 5 (H), 13 (*p*-Me), 34 (*p*-Et), 76 (*p*-*n*-Pr), 120 (*p*-*t*-Bu), and 520 M<sup>-1</sup> (*p*-*t*-Am).<sup>15</sup>

(23) The rate retarding effect of ionic strength on  $k_2$  was neglected in this qualitative comparison.
