## Reaction of *trans,trans*- $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$ with Lewis Acidic Boron Compounds. X-ray Structure of *trans*- $\text{W}(\eta^2\text{-BH}_4)(\text{CO})(\text{NO})(\text{PMe}_3)_2$

Adolphus A. H. van der Zeijden, Valery Shklover, and Heinz Berke\*

Received April 15, 1991

Reaction of the basic hydrides *trans,trans*- $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  ( $\text{R} = \text{Et}, \text{Me}, \text{Ph}, \text{O}i\text{Pr}$ ) with  $\text{BH}_3\cdot\text{L}$  ( $\text{L} = \text{THF}$  or  $\text{SMe}_2$ ) yields air-sensitive *trans*- $\text{W}(\eta^2\text{-BH}_4)(\text{CO})(\text{NO})(\text{PR}_3)_2$  as the main product, whereas the more acidic hydrides ( $\text{R} = \text{OMe}, \text{OPh}$ ) do not yield such a borohydride. The compounds  $\text{W}(\eta^2\text{-BH}_4)(\text{CO})(\text{NO})(\text{PR}_3)_2$  are unstable with respect to elimination of  $\text{BH}_3\cdot\text{PR}_3$  and could therefore only be characterized by spectroscopic methods. However, we succeeded in growing crystals of  $\text{W}(\eta^2\text{-BH}_4)(\text{CO})(\text{NO})(\text{PMe}_3)_2$ , which were studied by X-ray diffractive methods: space group  $\text{Pna}2_1$ ,  $a = 10.313$  (1) Å,  $b = 14.182$  (2) Å,  $c = 10.771$  (2) Å,  $Z = 4$ ,  $R = 0.0287$ , and  $R_w = 0.0289$  for 1167 reflections with  $F > 6\sigma(F)$ .

### Introduction

We have shown that the nitrosyl ligand in complexes of the type *trans,trans*- $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  causes a profound hydridic, i.e. basic, polarization of the *trans*-NO-positioned tungsten-hydride bond.<sup>1</sup> This is expressed in reactions of these complexes with mild acids like acetic acid and phenol, which result in facile elimination of dihydrogen. We have also shown that the hydridic character of these complexes can be further tuned by variation of the two *cis*-positioned phosphorus ligands.<sup>2</sup> Strongly  $\sigma$ -donating phosphines ( $\text{PEt}_3$ ,  $\text{PMe}_3$ ) were found to give more basic hydrides, whereas a strongly  $\pi$ -accepting phosphite, like  $\text{P}(\text{OPh})_3$ , gave a more acidic complex. Moreover, we were able to quantify the reactivity of the W-H bond, by correlating it to the  $\nu(\text{W-H})$  stretching frequency, which in turn could be correlated to Tolman's electronic parameter of the phosphorus ligands.<sup>3</sup> We were interested whether the hydridic character of  $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  was also expressed in its behavior toward Lewis acids and therefore decided to investigate its reactivity toward homoleptic boron compounds.

### Experimental Section

IR spectra were obtained on a Biorad FTS-45 spectrometer.  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra were measured on a Varian Gemini 200 spectrometer,  $^{31}\text{P}$  NMR on a Varian XL-200 spectrometer, and  $^{11}\text{B}$  on a Bruker AM-400-WB spectrometer. All reactions and manipulations were carried out under an atmosphere of dry nitrogen with freshly distilled solvents.  $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  complexes with  $\text{R} = \text{Et}$ ,<sup>2</sup>  $\text{Me}$ ,<sup>2</sup>  $\text{Ph}$ ,<sup>4</sup>  $\text{OMe}$ ,<sup>5</sup>  $\text{O}i\text{Pr}$ ,<sup>5</sup> and  $\text{OPh}$ <sup>5</sup> were synthesized according to published methods.

**Reaction of  $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  with  $\text{BH}_3\cdot\text{L}$  ( $\text{L} = \text{THF}, \text{SMe}_2$ ).** In a typical procedure, an orange solution of 0.2 mmol of the tungsten hydride in hexane (THF or toluene was used for  $\text{R} = \text{Ph}$  and  $\text{OPh}$ ) was cooled to  $-80^\circ\text{C}$  and 1.5–2 equiv of either  $\text{BH}_3\cdot\text{THF}$  (1 M in THF) or  $\text{BH}_3\cdot\text{SMe}_2$  (1 M in  $\text{CH}_2\text{Cl}_2$ ) were added. When the temperature was slowly raised to  $+20^\circ\text{C}$ , the clear reaction mixture turns red for  $\text{R} = \text{Ph}$  and  $\text{O}i\text{Pr}$  and violet for  $\text{R} = \text{Me}$  and  $\text{Et}$  between  $-20$  and  $-10^\circ\text{C}$ ,

while no color change was observed for R = OMe and OPh. The resulting very air-sensitive reaction mixtures were analyzed by IR and NMR spectroscopy. For R = Et, Me, Ph, and OiPr the compounds  $\text{W}(\eta^2\text{-BH}_4)(\text{CO})(\text{NO})(\text{PR}_3)_2$  and  $\text{BH}_3 \cdot \text{PR}_3$  were found to be the main constituents, poisoned by trace amounts of  $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  and other unknown tungsten compounds, while for R = OMe and OPh no tungsten borohydride compounds could be detected. Attempts to purify the tungsten borohydride compounds were frustrated by the fact that they slowly eliminate  $\text{BH}_3 \cdot \text{PR}_3$ , with concomitant formation of various tungsten-containing compounds, among which  $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  was identified.

Slow cooling of the crude reaction mixture of  $\text{WH}(\text{CO})_2(\text{NO})(\text{PMe}_3)_2$  and  $\text{BH}_3 \cdot \text{THF}$  in hexane to -80 °C resulted in the coprecipitation of dark purple crystals of  $\text{W}(\eta^2\text{-BH}_4)(\text{CO})(\text{NO})(\text{PMe}_3)_2$ , colorless crystals of  $\text{BH}_3 \cdot \text{PMe}_3$ , and a few orange crystals of  $\text{WH}(\text{CO})_2(\text{NO})(\text{PMe}_3)_2$ . The former ones turned out to be stable enough for an X-ray diffraction study at low temperature.

**Reaction of  $\text{WH}(\text{CO})_2(\text{NO})(\text{P}(\text{OiPr})_3)_2$  with  $\text{B}(\text{C}_6\text{F}_5)_3$ .** Syntheses of [*trans,trans*- $\text{W}(\text{CO})_2(\text{NO})(\text{P}(\text{OiPr})_3)_2(\text{S})$ ]<sup>+</sup>[ $\text{BH}(\text{C}_6\text{F}_5)_3$ ]<sup>-</sup> (S = Acetone, THF, Methanol). To a solution of 0.39 g (0.76 mmol) of  $\text{B}(\text{C}_6\text{F}_5)_3$  in 15 mL of acetone was added at room temperature 0.44 g (0.64 mmol) of  $\text{WH}(\text{CO})_2(\text{NO})(\text{P}(\text{OiPr})_3)_2$ . Instant formation of [*trans,trans*- $\text{W}(\text{CO})_2(\text{NO})(\text{P}(\text{OiPr})_3)_2(\text{acetone})$ ]<sup>+</sup>[ $\text{BH}(\text{C}_6\text{F}_5)_3$ ]<sup>-</sup> was observed spectroscopically. Evaporation of solvent and washing of the residue with petrol ether afforded 0.75 g (94%) of this salt as an orange oil, which was characterized by IR and NMR spectroscopy and MS. FAB-POS MS: *m/e* 686 (cation - acetone). EI-NEG MS: *m/e* 513 (anion).

Similarly, when the same reaction was conducted in solvents (S) like THF or methanol [*trans,trans*- $\text{W}(\text{CO})_2(\text{NO})(\text{P}(\text{OiPr})_3)_2(\text{S})$ ]<sup>+</sup>[ $\text{BH}(\text{C}_6\text{F}_5)_3$ ]<sup>-</sup> could be isolated in almost quantitative yield. However, if this reaction was conducted in dichloromethane, benzene, toluene, or hexane, decomposition was observed.

The same solvated cations can be synthesized by the reaction of  $\text{WH}(\text{CO})_2(\text{NO})(\text{P}(\text{OiPr})_3)_2$  with  $\text{Ph}_3\text{CPF}_6$ ,  $\text{HPF}_6$ ,  $\text{HBF}_4$ , or  $\text{BF}_3 \cdot \text{Et}_2\text{O}$  in the aforementioned coordinating solvents.

**Reaction of  $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  with Other Homoleptic Boron Compounds.** No reaction of  $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  with either  $\text{BEt}_3$ ,  $\text{B}(\text{OMe})_3$ , or  $\text{BPh}_3$  was observed in any solvent.

**X-ray Analysis of  $\text{W}(\eta^2\text{-BH}_4)(\text{CO})(\text{NO})(\text{PMe}_3)_2$ .** A suitable crystal was placed under argon in a glass capillary. Relevant data on the X-ray

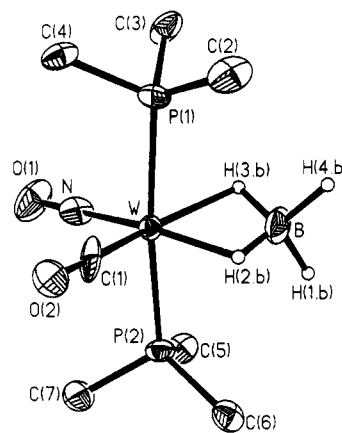

Figure 1. ORTEP diagram of *trans*- $\text{W}(\eta^2\text{-BH}_4)(\text{CO})(\text{NO})(\text{PMe}_3)_2$ . The ellipsoids are drawn to the 50% probability level except for the H atoms. The C-bound H atoms were omitted for clarity.

investigations are given in Table I. Lattice parameters were based on 24 centered reflections with  $2\theta$  values between 25 and 28°. The intensities of 1585 reflections with  $2 < 2\theta < 52^\circ$  were measured by using the  $\theta/2\theta$  scan technique on a Siemens P3 diffractometer using graphite-monochromated Mo K $\alpha$  radiation. Three check reflections, which were measured every 100 reflections, showed no decay during data collection. The structure was solved by automated heavy-atom methods and refined by full-matrix least-squares methods in anisotropic approximation for non-hydrogen atoms. The hydrogens of the Me groups were refined with constrained tetrahedral geometry (C-H = 0.96 Å,  $U_{\text{iso}} = 0.08 \text{ Å}^2$ ). The hydrogen atoms of the BH<sub>4</sub> unit could all be located but not refined successfully. They were therefore constrained to tetrahedral geometry with a refinable common value for the B-H distance and  $U_{\text{iso}} = 0.08 \text{ Å}^2$ . An empirical absorption correction was applied ( $\mu = 76.7 \text{ cm}^{-1}$ ) based on the azimuthal scan of equivalent reflections. The positional and thermal parameters of the non-hydrogen atoms are listed in Table II. All calculations were performed on a Microvax 2000 computer using the SHELXTL PLUS program package.<sup>6</sup>

## Results

The tungsten hydrides *trans,trans*- $\text{WH}(\text{CO})_2(\text{NO})(\text{PR}_3)_2$  (R = Et, Me, Ph, OMe, OiPr, OPh) reacted with 1.5–2 equiv of borane (as its THF or SMe<sub>2</sub> adduct) to produce purple (R = Et, Me), red (R = Ph, OiPr), or orange solutions (R = OMe, OPh). Spectroscopic analysis of these solutions (see Tables III and IV) show them to be mixtures of mainly *trans*- $\text{W}(\eta^2\text{-BH}_4)(\text{CO})(\text{NO})(\text{PR}_3)_2$  and the known  $\text{BH}_3 \cdot \text{PR}_3$  for R = Et, Me, Ph, and OiPr (Scheme 1), while for R = OMe and OPh only the borane-phosphite adduct could be observed in solution. The use of less of the aforementioned amount of  $\text{BH}_3 \cdot \text{L}$  leads to an incomplete conversion, whereas more  $\text{BH}_3 \cdot \text{L}$  increases the production of  $\text{BH}_3 \cdot \text{PR}_3$ .

The efficiency of the conversion of the tungsten hydride to the tungsten borohydride under optimal conditions, i.e. with 1.5–2 equiv of borane, was estimated (by <sup>1</sup>H NMR) to be 40–60 % at best. The fact that more than 1 equiv of borane is needed to drive the reaction to completion, suggests that the attack of borane proceeds not exclusively on the hydride atom but also on the

W-B	2.36 (2)	C1-O2	1.17 (5)

adjacent carbonyl and/or phosphine ligands, resulting in partial decomposition of the tungsten hydride. Attempts to isolate the tungsten borohydrides were frustrated by the fact that these compounds slowly eliminate BH<sub>3</sub>·PR<sub>3</sub> in solution. Their identification is therefore mainly based on spectroscopic evidence in solvent media. However, by slowly cooling down the crude reaction mixture of WH(CO)<sub>2</sub>(NO)(PMe<sub>3</sub>)<sub>2</sub> and BH<sub>3</sub>·THF in hexane, we succeeded in growing single crystals of W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)(PMe<sub>3</sub>)<sub>2</sub> corroborating our spectroscopic findings (vide infra).

The IR spectra (Table III) of W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)(PR<sub>3</sub>)<sub>2</sub> show the presence of one NO and one CO ligand, as well as absorptions arising from terminal BH bonds (bands for bridging BH's could not be assigned with certainty, due to overlap with those of the phosphorus ligand).

The <sup>13</sup>C NMR spectra of W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)(PR<sub>3</sub>)<sub>2</sub> show a triplet splitting <sup>2</sup>J(<sup>13</sup>C-<sup>31</sup>P) of the carbonyl carbon, confirming the presence of two, mutually trans-positioned phosphorus ligands cis to the carbonyl. No carbonyl-hydride coupling, <sup>2</sup>J(<sup>1</sup>H-<sup>13</sup>C), could be observed, even at -80 °C; in the parent complex, WH(CO)<sub>2</sub>(NO)(PR<sub>3</sub>)<sub>2</sub> this coupling amounts to ca. 10 Hz.<sup>2</sup>

The <sup>11</sup>B NMR spectra show a broad featureless signal (unchanged from +20 to -80 °C) at around 0 ppm, from which no information concerning the bonding mode of the tetrahydroborate group can be extracted.

The (<sup>11</sup>B-decoupled) <sup>1</sup>H NMR spectra, taken at room temperature, did not reveal the resonances of the borohydride group of either of the four tungsten complexes. This is probably due to severe broadening of those signals by <sup>11</sup>B quadrupolar relaxation. Even at -80 °C in CD<sub>2</sub>Cl<sub>2</sub>, we were not able to detect these signals for the PET<sub>3</sub> and PMe<sub>3</sub> derivatives. For W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)(PPh<sub>3</sub>)<sub>2</sub>, however, we observed at that temperature very broad signals at ca. -2.7, -1.6, and +4.0 ppm, while for W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)[P(OiPr)<sub>3</sub>]<sub>2</sub> well resolved, but still broad singlets could be observed at -3.71, -2.58, and +4.61 ppm in a 1:1:2 integral ratio. These data indicate the presence of an  $\eta^2$ -bonded BH<sub>4</sub> unit, the low-field signal being associated with the two terminal H atoms and both high-field signals with the ones bridging between tungsten and boron. One of these H atoms must therefore be trans positioned to the CO ligand, the other one trans to NO. The absence of a mirror plane running through the phosphorus atoms was demonstrated by the appearance of two signals for the diastereotopic methyl groups in the W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)[P(OiPr)<sub>3</sub>]<sub>2</sub> complex.

The spectroscopic findings on the structure of W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)(PR<sub>3</sub>)<sub>2</sub> were confirmed by an X-ray diffraction study on W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)(PMe<sub>3</sub>)<sub>2</sub>, an ORTEP view of which is shown in Figure 1.

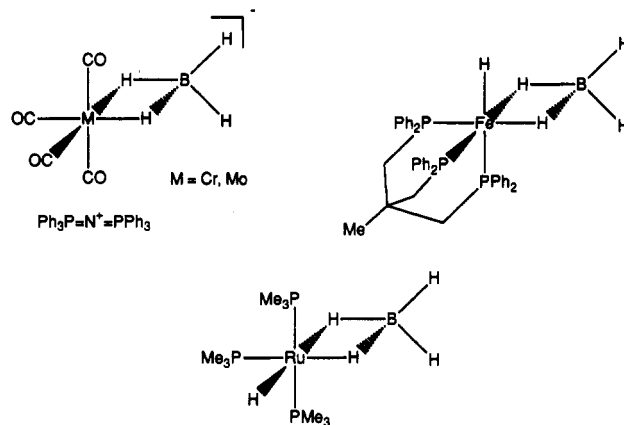

Relevant bond lengths and angles are given in Tables V and VI, respectively. It is noticed that the tetrahydroborate group was refined as a constrained regular tetrahedron, and therefore the geometry of this group and its coordination must be considered with some care. The coordination around tungsten may be described as distorted octahedral. The W and B atom, as well as the NO and CO ligands lie in one plane (maximum deviation 0.03 Å). The P-W-P vector is almost rectangular to this plane. Although the CO and NO ligands fit in the octahedral description of the molecule ( $\angle$ C-W-N = 94 (1)°), the coordination of the BH<sub>4</sub> unit presents the major distortion from this ideal geometry. The BH<sub>4</sub> unit occupies, through two bridging hydrogens, two coordination sites around tungsten, but is thereby forced to a very small H-W-H bite angle of 64 (4)°. The boron atom slightly deviates from the axis bisecting the N-W-C(1) bond angle ( $\angle$ N-W-B = 139 (1) and  $\angle$ C-W-B = 127 (2)°).

The bidentate coordination of BH<sub>4</sub> in our complex shows a resemblance to that of other isolobal octahedral d<sup>6</sup> compounds

like [Ph<sub>3</sub>PNPPh<sub>3</sub>]<sup>+</sup>[M( $\eta^2$ -BH<sub>4</sub>)(CO)<sub>4</sub>]<sup>-</sup> (M = Cr,<sup>7</sup> and Mo<sup>8</sup>), fac-FeH( $\eta^2$ -BH<sub>4</sub>)[MeC(CH<sub>2</sub>PPh<sub>2</sub>)<sub>3</sub>]<sub>3</sub>,<sup>9</sup> and mer-RuH( $\eta^2$ -BH<sub>4</sub>)(PMe<sub>3</sub>)<sub>3</sub>:

A striking feature of all these structures is that the boron atom is found slightly displaced from the axis bisecting the two opposing trans ligands, even in the symmetrical [Cr( $\eta^2$ -BH<sub>4</sub>)(CO)<sub>4</sub>]<sup>-</sup> anion.<sup>7</sup>

EHT calculations<sup>11</sup> on the model compound trans-W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)(PH<sub>3</sub>)<sub>2</sub> show that an asymmetrical bonding mode of the  $\eta^2$ -BH<sub>4</sub> unit is indeed preferred. Consistent with the findings of the X-ray structure analysis on trans-W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)(PMe<sub>3</sub>)<sub>2</sub> a bending of the whole BH<sub>4</sub> moiety toward the CO group occurs. This may be explained by analyzing the binding abilities of the [W(CO)(NO)(PH<sub>3</sub>)<sub>2</sub>]<sup>+</sup> fragment, whose frontier orbitals can principally be derived from those of a C<sub>2v</sub> ML<sub>4</sub> system.<sup>12</sup> The lowered symmetry in the C<sub>s</sub> [W(CO)(NO)(PH<sub>3</sub>)<sub>2</sub>]<sup>+</sup> moiety does not change the fundamental "2 above 3" orbital situation of a C<sub>2v</sub> ML<sub>4</sub> fragment; however, it induces perturbations with concomitant tilting of both of the high-lying "a<sub>1</sub>" and "b<sub>2</sub>" fragmental lobes toward the CO group, as sketched by the following schematic representation:

**Scheme II**

Intuitively, it is somewhat surprising that “a<sub>1</sub>” and “b<sub>2</sub>” get polarized in such a way that they both turn the same direction. The unexpected behavior in rotation is the one of “a<sub>1</sub>”. In [W(CO)(NO)(PH<sub>3</sub>)<sub>2</sub>]<sup>+</sup>, “a<sub>1</sub>” is found to be preferentially mixed with an in-plane  $\pi^*$  combination of the  $\pi$  acceptor ligands, which also contains some d and p orbital character of the tungsten center. The direction of the rotation is set by the tendency to minimize antibonding contact between orbital character at the tungsten and the stronger  $\pi$  acceptor ligand, which carries quite pronounced orbital coefficients. The  $\eta^2$ -[BH<sub>4</sub>]<sup>-</sup> ligand may be viewed as a single-faced  $\pi$ -donor offering two filled orbitals for interaction with “a<sub>1</sub>” and “b<sub>2</sub>”. For maximum interaction, the BH<sub>4</sub> unit has to seek a position rotated in the same direction as “a<sub>1</sub>” and “b<sub>2</sub>”.

The X-ray structures of W( $\eta^2$ -BH<sub>4</sub>)(CO)(NO)(PMe<sub>3</sub>)<sub>2</sub> and of the starting compound WH(CO)<sub>2</sub>(NO)(PMe<sub>3</sub>)<sub>2</sub> show the following differences: (1) Both the W-N and W-C distances are ca. 0.1 Å shorter in the borohydride complex. This is because the substitution of one of three  $\pi$ -accepting ligands through a  $\sigma$ -donating H atom in the W(CO)<sub>2</sub>(NO)H plane causes a more efficient distribution of  $\pi$ -electron density to the remaining two CO and NO ligands. On the other hand the W-P, C-O, and N-O bond lengths are similar in the two structures. (2) In the tungsten hydride the phosphine ligands are bent toward the hydride atom ( $\angle\text{P-W-P} = 164.4$  (1)°), while in the borohydride they are only slightly bent toward the boron atom ( $\angle\text{P-W-P} = 174.0$  (1)°).

**Reaction of WH(CO)<sub>2</sub>(NO)(PR<sub>3</sub>)<sub>2</sub> with Other Homoleptic Boron Compounds.** No reaction was observed of WH(CO)<sub>2</sub>(NO)(PR<sub>3</sub>)<sub>2</sub> with the weaker Lewis acids BEt<sub>3</sub>, B(OMe)<sub>3</sub>, and BPh<sub>3</sub>. The stronger Lewis acid B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> reacted with the tungsten hydride (only investigated for the P(OiPr)<sub>3</sub> derivative), with abstraction of the hydride atoms and production of a solvated tungsten cation (Scheme II).

The product *trans,trans*-[W(S)(CO)<sub>2</sub>(NO)[P(OiPr)<sub>3</sub>]<sub>2</sub>][BH(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub>] was found to be stable and isolable only when the reaction was conducted in a coordinating solvent, like acetone, THF, or methanol. The  $^1\text{H}$  and  $^{31}\text{P}$  NMR data for these cations are listed in Table VII. Strong coordination of solvent molecules is anticipated because of (1) slow exchange of coordinated and free solvent molecules (NMR) and (2) the observation of a  $^{31}\text{P}$  triplet coupling (1.1 Hz) of the acetone hydrogens in the [W(acetone)(CO)<sub>2</sub>(NO)[P(OiPr)<sub>3</sub>]<sub>2</sub> cation.

The same cations could be obtained by reaction of WH(CO)<sub>2</sub>(NO)[P(OiPr)<sub>3</sub>]<sub>2</sub> with either Ph<sub>3</sub>CPF<sub>6</sub>, HPF<sub>6</sub>, HBF<sub>4</sub>, or BF<sub>3</sub>·Et<sub>2</sub>O.
